Rate Region of Gaussian Multiple Description Coding With Individual and Central Distortion Constraints

Jun Chen, Member, IEEE

Abstract—The rate region of Gaussian multiple description coding with individual and central distortion constraints is completely characterized. Specifically, a lower bound and an upper bound are derived for each supporting hyperplane of the rate region, where the lower bound is associated with a max-min game while the upper bound is associated with a min-max game; furthermore, it is shown that these two bounds coincide due to the existence of a saddle point.

Index Terms—Contra-polymatroid, entropy power inequality, min-max, multiple description coding, saddle point.

I. INTRODUCTION

MULTIPLE description coding is a quantization technique developed for multimedia transmission through unreliable links. In the standard setting of the multiple description problem, several coded representations are formed for the target source such that any subset of these representations can be used to reconstruct the source with certain fidelity. Each representation is referred to as a description, and the goal is to find the optimal tradeoff between the code rates of the descriptions and the reconstruction distortions.

The first general result on the multiple description problem is the 2-description achievable rate region by El Gamal and Cover (EGC) [1], which is based on the idea of correlated quantization. This result has been extended to the general L-description case in [2]. It is observed in [3] and [4] that the EGC achievable rate region can be enlarged by coupling correlated quantization with the binning technique. Further improvements can be found in [5].

Although the general multiple description problem is still widely open, several conclusive results have been obtained for the quadratic Gaussian case. Notably, when only individual and central distortion constraints are imposed, the minimum achievable rate region has been derived by Ozarow for the 2-description case [6] and by Wang and Viswanath for the general L-description case [7] (see also [2] for the symmetric case). Moreover, the minimum achievable sum-rate together with two trivial bounds on the individual rates yields an exact characterization of the rate region for the 2-description case [6]. However, the rate region of Gaussian multiple description coding with individual and central distortion constraints for the general L-description case is still unknown. The key contribution of the present work is a complete solution to this open problem.

Throughout this paper, the logarithm function is to base $e$. We use $I_n$ to denote an $n \times n$ identity matrix and use $A^n$ to denote an $n$-dimensional random vector $(A(1), \ldots, A(n))$ for any positive integer $n$. The operators $E(\cdot)$ and $\text{tr}(\cdot)$ denote expectation and trace, respectively. For random vectors $A^n$ and $B^m$, the conditional expectation of $A^n$ given $B^m$ is denoted by $E(A^n | B^m)$ and the covariance matrix of $A^n - E(A^n | B^m)$ is denoted by $\text{cov}(A^n | B^m)$ with a slight abuse of notation, we interpret $\text{cov}(A^n | B^m)$ as $\text{tr}([\text{cov}(A^n | B^m)])$ when $n = 1$. We use the convention that $\frac{1}{\infty} = 0$, $\log 0 = -\infty$, and $0 \log 0 = 0$.

II. PROBLEM SETTING AND MAIN RESULTS

Let $\{X(m)\}_{m=1}^\infty$ be a stationary and memoryless Gaussian process with mean zero and variance $\sigma^2_X$. Given individual distortion constraints $d(i), i = 1, \ldots, L$, and central distortion constraint $d_{\{1,\ldots,L\}}$, we say a rate vector $(R_1, \ldots, R_L)$ is achievable if there exist, for all sufficiently large $n$, encoding functions $f_i^{(n)} : \mathbb{R}^n \rightarrow \mathbb{C}^i$ with $\frac{1}{n} \log |C_i^{(n)}| \leq R_i$, $i = 1, \ldots, L$, such that

$$\frac{1}{n} \text{tr} \left( \text{cov} \left( X^n | f_i^{(n)}(X^n) \right) \right) \leq d(i), \quad i = 1, \ldots, L,$$

$$\frac{1}{n} \text{tr} \left( \text{cov} \left( X^n | f_1^{(n)}(X^n), \ldots, f_L^{(n)}(X^n) \right) \right) \leq d_{\{1,\ldots,L\}}.$$

The rate region $\mathcal{R}(d_1, \ldots, d_L, d_{\{1,\ldots,L\}})$ is the convex closure of the set of all achievable rate vectors with respect to individual distortion constraints $d_i, i = 1, \ldots, L$, and central distortion constraint $d_{\{1,\ldots,L\}}$. Without loss of generality, we shall assume $0 < d_1, \ldots, d_L, d_{\{1,\ldots,L\}} \leq \sigma^2_X$.

Since $\mathcal{R}(d_1, \ldots, d_L, d_{\{1,\ldots,L\}})$ is a closed convex set, it suffices to characterize its supporting hyperplanes, which boils down to solving the following optimization problem:

$$\min_{(R_1, \ldots, R_L) \in \mathcal{R}(d_1, \ldots, d_L, d_{\{1,\ldots,L\}})} \sum_{i=1}^L \alpha_i R_i \quad (1)$$

where $\alpha_i, i = 1, \ldots, L$, are arbitrary nonnegative numbers. It is clear that through suitable relabeling, we may assume, with no loss of generality, that $\alpha_1 \geq \cdots \geq \alpha_L$. Moreover, if $\alpha_L = 0$, then we can allocate enough rate to description $L$ to meet the individual distortion constraint $d_L$ and the central distortion constraint $d_{\{1,\ldots,L\}}$ without affecting the weighted sum-rate while
the other descriptions only need to meet their corresponding individual distortion constraints; as a consequence, it follows from the classic rate-distortion theory that
\[
\min_{(R_1, \ldots, R_L) \in \mathcal{R}(d_1, \ldots, d_L, d_{[1, \ldots, L]})} \sum_{i=1}^L \alpha_i R_i = \frac{1}{2} \sum_{i=1}^L \alpha_i \log \left( \frac{\sigma_i^2}{d_{[i]}} \right) \\
= \frac{1}{2} \sum_{i=1}^L \alpha_i \log \left( \frac{\sigma_i^2}{d_{[i]}} \right).
\]

Therefore, we shall assume \( \alpha_1 \geq \cdots \geq \alpha_L > 0 \) in the rest of this paper.

Note that when \( \alpha_1 = \cdots = \alpha_L \), the optimization problem (1) yields the minimum sum-rate (up to a scalar) of the rate region \( \mathcal{R}(d_1, \ldots, d_L, d_{[1, \ldots, L]}) \). Specifically, it is known [6], [7] that
\[
\min_{(R_1, \ldots, R_L) \in \mathcal{R}(d_1, \ldots, d_L, d_{[1, \ldots, L]})} \sum_{i=1}^L R_i = \sup_{\sigma^2 > 0} \frac{1}{2} \log \left( \frac{\sigma_1^2 \left( \sigma_2^2 + \sigma_3^2 \right)^{L-1} d_{[1, \ldots, L]} + \sigma_2^2}{\prod_{i=1}^L d_{[i]} + \sigma_2^2} \right),
\]

However, the technique used to derive (2) is not sufficient for characterizing other supporting hyperplanes. The main reason is as follows. To minimize the achievable sum-rate of the EGC scheme, the covariance matrix of the quantization errors associated with different descriptions has the property that all the off-diagonal entries are identical and nonpositive. As shown by the ingenious converse argument devised by Ozarow [6] (see also [7]), this property can be effectively exploited to create a conditional independence structure by introducing a hidden auxiliary random vector. Remarkably, the resulting lower bound coincides with the minimum EGC achievable sum-rate. Unfortunately, when optimizing the EGC achievable scheme for other hyperplanes, the corresponding covariance matrix of the quantization errors in general does not have this simple structure. As a consequence, a direct application of Ozarow’s argument does not lead to a matching lower bound, and more sophisticated techniques are needed.

To the end of solving the optimization problem (1), we shall introduce several auxiliary distortion constraints in addition to the individual and central distortion constraints. We say the weighted sum-rate \( R \) is achievable with respect to individual distortion constraints \( d_{[i]}, i = 1, \ldots, L \), auxiliary distortion constraints \( d_{[1], \ldots, L]} \), \( i = 2, \ldots, L - 1 \), and central distortion constraint \( d_{[1, \ldots, L]} \), if there exist, for all sufficiently large \( n \), encoding functions \( f_i^{(n)} : \mathcal{R} \rightarrow \mathcal{C}^{(n)}_i, i = 1, \ldots, L \), with

\[
\frac{1}{n} \sum_{i=1}^L \alpha_i \log |\mathcal{C}^{(n)}_i| \leq R \text{ such that } \frac{1}{n} \text{tr} \left( \text{cov} \left( X^n | f_i^{(n)}(X^n) \right) \right) \leq d_{[i]}^{(n)}, i = 1, \ldots, L,
\]

\[
\frac{1}{n} \text{tr} \left( \text{cov} \left( X^n | f_i^{(n)}(X^n), \ldots, f_{i+1}^{(n)}(X^n) \right) \right) \leq d_{[i], \ldots, L]}^{(n)}, i = 2, \ldots, L - 1,
\]

\[
\frac{1}{n} \text{tr} \left( \text{cov} \left( X^n | f_1^{(n)}(X^n), \ldots, f_L^{(n)}(X^n) \right) \right) \leq d_{[1, \ldots, L]}^{(n)}.
\]

Let \( \kappa(d_1, \ldots, d_L, d_{[1, 2]}, \ldots, d_{[1, \ldots, L-1]}, d_{[1, \ldots, L]}) \) be the infimum of all achievable weighted sum-rate \( R \) with respect to individual distortion constraints \( d_{[i]}, i = 1, \ldots, L \), auxiliary distortion constraints \( d_{[i], \ldots, L]}^{(n)}, i = 2, \ldots, L - 1 \), and central distortion constraint \( d_{[1, \ldots, L]}^{(n)} \). Without loss of generality, we shall assume \( 0 < d_{[1, 2]} \leq \cdots \leq d_{[1, \ldots, L-1]} \leq \sigma_X^2 \). Note that the auxiliary distortion constraints are void if \( L = 2 \).

We define \( \psi(\cdot) \) shown at the bottom of the page. The importance of this function is evident from the following theorems.

**Theorem 1:** We have
\[
\kappa(d_1, \ldots, d_L, d_{[1, 2]}, \ldots, d_{[1, \ldots, L-1]}, d_{[1, \ldots, L]}) \geq \max_{\sigma^2 \in [0, \sigma_X^2], i = 2, \ldots, L-1} \min_{i = 1, \ldots, L} \min_{d_{[i], \ldots, L]} \psi(d_1, \ldots, d_L, d_{[1, 2]}, \ldots, d_{[1, \ldots, L]}, \sigma^2_i, \ldots, \sigma^2_{L-1}) .
\]

Therefore, \( \kappa(d_1, \ldots, d_L, d_{[1, 2]}, \ldots, d_{[1, \ldots, L-1]}, d_{[1, \ldots, L]}) \) can be lower-bounded using a max-min game. Interestingly, the corresponding min-max game yields an upper bound on \( \kappa(d_1, \ldots, d_L, d_{[1, 2]}, \ldots, d_{[1, \ldots, L-1]}, d_{[1, \ldots, L]}) \).

**Theorem 2:** We have (4) shown at the bottom of the page.
It turns out that max-min (cf. (3)) and min-max (cf. (4)) coincide, yielding a complete characterization of $\kappa(d_{1}, \ldots, d_{L}, d'_{1, 2}, \ldots, d'_{1, m-1, L-1}, d'_{1, \ldots, L})$.

Theorem 3: We have the first set of equations shown at the bottom of the following page.

One can immediately obtain the following result by setting $d'_{1, \ldots, i} = \sigma_{Y, i}^{2}$, $i = 2, \ldots, L - 1$, to make the auxiliary distortion constraints redundant.

Theorem 4: We have the second set of equations shown at the bottom of the page.

As a side note, the rate region $\mathcal{R}(d_{1}, \ldots, d_{L}, d'_{1, \ldots, L})$ is achievable using the lattice quantization scheme (possibly with timesharing) developed in [8] and [9].

It will be seen that besides Ozarow’s method of creating conditional independence structure, several new ingredients are needed to prove these theorems, which include

- an application of Costa’s entropy power inequality [10],
- multiple auxiliary random vectors,
- saddle point analysis of a max-min/min-max game,
- a delicate construction of the covariance matrix of the quantization errors for the EGC achievable scheme.

The remainder of this paper is divided into four sections. The proofs of Theorem 1, Theorem 2, and Theorem 3 are given in Sections III, IV, and V, respectively. We conclude the paper in Section VI.

III. LOWER BOUND: PROOF OF THEOREM 1

The following lemma is of crucial importance for establishing the desired lower bound.

Lemma 1: Let $N_{1}^{n}$ and $N_{2}^{n}$ be two $n$-dimensional Gaussian random vectors with positive definite covariance matrices $\Sigma_{1}^{n}$ and $\Sigma_{2}^{n}$, respectively. Let $\mu_{2} \geq \mu_{1} \geq 0$ be two real numbers. For any $n$-dimensional random vector $S^{n}$ and random variable $T$, both independent of $N_{1}^{n}$ and $N_{2}^{n}$, such that $\operatorname{tr}(\operatorname{cov}(S^{n} \mid T)) \leq n \mu_{1}$, we have

$$\mu_{1} h(S^{n} + N_{1}^{n} \mid T) - \mu_{2} h(S^{n} + N_{2}^{n} \mid T) + (\mu_{2} - \mu_{1}) h(S^{n} \mid T) \leq \frac{\mu_{1} n}{2} \log \left(\frac{d + \sigma^{2}}{\mu_{1}}\right) - \frac{\mu_{2} n}{2} \log \left(\frac{d + \sigma^{2}}{\mu_{2}}\right) + \frac{(\mu_{2} - \mu_{1}) n}{2} \log(d)$$

(5)

where $h(\cdot)$ is the differential entropy function.

Remark: It is worth noting that the maximum in (5) is not necessarily attained at $d = d'$. Proof: See Appendix A.

Now we proceed to derive a lower bound on $\kappa(d_{1}, \ldots, d_{L}, d'_{1, 2}, \ldots, d'_{1, m-1, L-1}, d'_{1, \ldots, L})$. Let $f^{(n)}_{i} : \mathcal{R}^{n} \rightarrow \mathbb{C}_{i}^{(n)}$, $i = 1, \ldots, L$, be $L$ arbitrary encoding functions satisfying

$$\frac{1}{n} \operatorname{tr} \left( \operatorname{cov} \left( X^{n} \mid f^{(n)}_{i}(X^{n}) \right) \right) \leq d_{i}, \quad i = 1, \ldots, L,$$

$$\frac{1}{n} \operatorname{tr} \left( \operatorname{cov} \left( X^{n} \mid f^{(n)}_{1}(X^{n}), \ldots, f^{(n)}_{L}(X^{n}) \right) \right) \leq d_{1, \ldots, i}, \quad i = 2, \ldots, L - 1,$$

$$\frac{1}{n} \operatorname{tr} \left( \operatorname{cov} \left( X^{n} \mid f^{(n)}_{1}(X^{n}), \ldots, f^{(n)}_{L}(X^{n}) \right) \right) \leq d_{1, \ldots, L}.$$

Define $C_{i} = f^{(n)}_{i}(X^{n})$, $i = 1, \ldots, L$. Note that

$$\sum_{i=1}^{L} \alpha_{i} \log |C_{i}|^{n} \geq \sum_{i=1}^{L} \alpha_{i} H(C_{i}) = \sum_{j=1}^{L} \left( \alpha_{i} - \alpha_{i+1} \right) H(C_{j})$$

(6)

where $\alpha_{L+1} \triangleq 0$. It is easy to verify that

$$\sum_{j=1}^{L} H(C_{j}) = H(C_{1}, \ldots, C_{L}) + \sum_{j=1}^{L} I(C_{1}, \ldots, C_{j}; C_{j+1})$$

$$= I(X^{n}; C_{1}, \ldots, C_{L}) + \sum_{j=1}^{L} I(C_{1}, \ldots, C_{j}; C_{j+1}),$$

$$i = 2, \ldots, L.$$  

(7)
Substituting (7) into (6), we obtain
\[
\sum_{i=1}^{L} \alpha_i \log \left| C_i^{(n)} \right| \\
\geq \sum_{i=1}^{L} (\alpha_i - \alpha_{i+1}) I(X^n; C_1, \ldots, C_i) \\
+ \sum_{i=2}^{L} (\alpha_i - \alpha_{i+1}) \sum_{j=1}^{i-1} I(C_1, \ldots, C_j; C_{j+1}) \\
= \sum_{i=1}^{L} (\alpha_i - \alpha_{i+1}) I(X^n; C_1, \ldots, C_i) \\
+ \sum_{i=2}^{L} \alpha_i I(C_1, \ldots, C_{i-1}; C_i), \tag{8}
\]

Let \( Z^n_1, \ldots, Z^n_{L-1} \) be zero-mean \( n \)-dimensional Gaussian random vectors with covariance matrices \( \sigma^2_{Z_1} I_n, \ldots, \sigma^2_{Z_{L-1}} I_n \), respectively. We have
\[
I(C_1, \ldots, C_{i-1}; C_i) \\
= I(X^n + Z^n_{i-1}; C_1, \ldots, C_{i-1}) + I(X^n + Z^n_{i-1}; C_i) \\
+ I(C_1, \ldots, C_{i-1}; C_i | X^n + Z^n_{i-1}) \\
- I(X^n + Z^n_{i-1}; C_1, \ldots, C_{i-1}) \\
\geq I(X^n + Z^n_{i-1}; C_1, \ldots, C_{i-1}) \\
+ I(X^n + Z^n_{i-1}; C_i) \\
- I(X^n + Z^n_{i-1}; C_1, \ldots, C_{i-1})
\]

which, together with (8), yields
\[
\sum_{i=1}^{L} \alpha_i \log \left| C_i^{(n)} \right| \\
\geq \sum_{i=1}^{L} (\alpha_i - \alpha_{i+1}) I(X^n; C_1, \ldots, C_i) \\
+ \sum_{i=2}^{L} \alpha_i I(X^n + Z^n_{i-1}; C_1, \ldots, C_{i-1}) \\
+ I(X^n + Z^n_{i-1}; C_i) \\
- I(X^n + Z^n_{i-1}; C_1, \ldots, C_{i-1}) \\
= (\alpha_1 - \alpha_2) I(X^n; C_1) + \alpha_2 I(X^n + Z^n_1; C_1) \\
+ \sum_{i=1}^{L-1} (\alpha_{i+1} I(X^n + Z^n_{i}; C_1, \ldots, C_i) \\
- \alpha_i I(X^n + Z^n_{i-1}; C_1, \ldots, C_i) \\
+ (\alpha_i - \alpha_{i+1}) I(X^n; C_1, \ldots, C_i) \\
- \alpha_i I(X^n + Z^n_{i-1}; C_1, \ldots, C_i) \\
+ \alpha_i I(X^n + Z^n_{i-1}; C_1, \ldots, C_L) \\
+ \alpha_L I(X^n; C_1, \ldots, C_L). \tag{9}
\]

Note that
\[
\text{tr}(\text{cov}(X^n | C_1)) \leq nd_{[1]}.
\]

By the rate-distortion theorem
\[
I(X^n; C_1) \geq \frac{n}{2} \log \left( \frac{\sigma^2_X}{d_{[1]}} \right), \tag{10}
\]

\[
I(X^n + Z^n_1; C_1) \geq \frac{n}{2} \log \left( \frac{\sigma^2_X + \sigma^2_{Z_1}}{d_{[1]} + \sigma^2_{Z_1}} \right), \tag{11}
\]

\[
I(X^n + Z^n_i; C_{i+1}) \geq \frac{n}{2} \log \left( \frac{\sigma^2_X + \sigma^2_{Z_{i-1}}}{d_{[i+1]} + \sigma^2_{Z_i}} \right), \quad i = 1, \ldots, L - 1. \tag{12}
\]

Moreover, we have
\[
\alpha_{i+1} I(X^n + Z^n_i; C_1, \ldots, C_i) \\
- \alpha_i I(X^n + Z^n_i; C_1, \ldots, C_i) \\
+ (\alpha_i - \alpha_{i+1}) I(X^n; C_1, \ldots, C_i)
\]

\[
= \alpha_{i+1} h(X^n + Z^n_i) - \alpha_i h(X^n + Z^n_i) \\
+ (\alpha_i - \alpha_{i+1}) h(X^n)
\]

\[
= \alpha_{i+1} h(X^n + Z^n_i | C_1, \ldots, C_i) \\
+ \alpha_i h(X^n + Z^n_i | C_1, \ldots, C_i) \\
- (\alpha_i - \alpha_{i+1}) h(X^n | C_1, \ldots, C_i)
\]

\[
= \frac{\alpha_{i+1} n}{2} \log (\sigma^2_X + \sigma^2_{Z_1}) \\
- \frac{\alpha_i n}{2} \log (\sigma^2_X + \sigma^2_{Z_{i-1}}) \\
+ \frac{\alpha_i - \alpha_{i+1}}{2} n \log (d_{[1]}) \\
- \alpha_{i+1} h(X^n + Z^n_i | C_1, \ldots, C_i) \\
+ \alpha_i h(X^n + Z^n_i | C_1, \ldots, C_i) \\
- (\alpha_i - \alpha_{i+1}) h(X^n | C_1, \ldots, C_i), \tag{13}
\]

Since \( \text{tr}(\text{cov}(X^n | C_1, \ldots, C_i)) \leq nd_{[1,i]} \), it follows from Lemma 1 that
\[
\alpha_{i+1} h(X^n + Z^n_i | C_1, \ldots, C_i) \\
- \alpha_i h(X^n + Z^n_i | C_1, \ldots, C_i) \\
+ (\alpha_i - \alpha_{i+1}) h(X^n | C_1, \ldots, C_i)
\]

\[
\leq \max_{d_{[1,i-1]}} \frac{\alpha_{i+1} n}{2} \log (d_{[1,i-1]}) + \sigma^2_{Z_i} \\
- \frac{\alpha_i n}{2} \log (d_{[1,i-1]}) + \sigma^2_{Z_{i-1}} \\
+ \frac{\alpha_i - \alpha_{i+1}}{2} n \log (d_{[1,i-1]}), \tag{14}
\]

Plugging (14) into (13), we obtain
\[
\alpha_{i+1} I(X^n + Z^n_i; C_1, \ldots, C_i) \\
- \alpha_i I(X^n + Z^n_i; C_1, \ldots, C_i) \\
+ (\alpha_i - \alpha_{i+1}) I(X^n; C_1, \ldots, C_i)
\]
Similarly, since \( \text{tr}(\text{cov}(X^n | C_1, \ldots, C_L)) \leq nd_1(1, \ldots, L) \), it follows from Lemma 1 that

\[
-\alpha_L h(X^n + Z_{l-1} | C_1, \ldots, C_L) + \alpha_L h(X^n | C_1, \ldots, C_L) \leq \frac{\alpha_L n}{2} \log \frac{d_1(1, \ldots, L) + \sigma_{Z_{l-1}}^2}{d_1(1, \ldots, L)}.
\]

Therefore, we have

\[
-\alpha_L I(X^n + Z_{l-1}; C_1, \ldots, C_L) + \alpha_L I(X^n; C_1, \ldots, C_L) = -\alpha_L h(X^n + Z_{l-1}) + \alpha_L h(X^n | Z_{l-1}) - \alpha_L h(X^n | C_1, \ldots, C_L) + \frac{\alpha_L n}{2} \log \frac{d_1(1, \ldots, L) + \sigma_{Z_{l-1}}^2}{d_1(1, \ldots, L)} = \frac{\alpha_L n}{2} \log \frac{\sigma_X^2}{\sigma_X^2 + \sigma_{Z_{l-1}}^2}.
\]

Substituting (10), (11), (12), (15), and (16) into (9), we get

\[
\frac{1}{n} \sum_{i=1}^{L} \alpha_i \log \left| C_i^n \right| \geq \frac{1}{n} \sum_{i=1}^{L} \min_{d_1(1, \ldots, L) \geq 2, \ldots, L-1} \phi \left( d_1(1, \ldots, L), d_i(1, \ldots, L), d_i(1, \ldots, L) \right) \leq \frac{1}{n} \sum_{i=1}^{L} \min_{d_1(1, \ldots, L) \geq 2, \ldots, L-1} \phi \left( d_1(1, \ldots, L), d_i(1, \ldots, L), d_i(1, \ldots, L), \sigma_{Z_{l-1}}^2, \sigma_{Z_{l-1}}^2, \sigma_{Z_{l-1}}^2, \sigma_{Z_{l-1}}^2 \right)
\]

where

\[
\phi \left( d_1(1, \ldots, L), d_i(1, \ldots, L), d_i(1, \ldots, L), \sigma_{Z_{l-1}}^2, \sigma_{Z_{l-1}}^2, \sigma_{Z_{l-1}}^2, \sigma_{Z_{l-1}}^2 \right) = \frac{1}{L-1} \sum_{i=1}^{L-1} \left( \frac{\alpha_i - \alpha_{i+1}}{2} \log \frac{\sigma_X^2}{d_1(1, \ldots, i)} + \frac{\alpha_{i+1}}{2} \log \left( \frac{d_i(1, \ldots, i) + \sigma_{Z_{l-1}}^2}{d_i(1, \ldots, i) + \sigma_{Z_{l-1}}^2} \right) \right) + \frac{\alpha_L}{2} \log \frac{\sigma_X^2}{d_1(1, \ldots, L)}.
\]

Since \( \sigma_{Z_j}^2, j = 1, \ldots, L-1 \), can be arbitrary positive numbers, it follows that

\[
\frac{1}{n} \sum_{i=1}^{L} \min_{d_1(1, \ldots, L) \geq 2, \ldots, L-1} \phi \left( d_1(1, \ldots, L), d_i(1, \ldots, L), d_i(1, \ldots, L), \sigma_{Z_{l-1}}^2, \sigma_{Z_{l-1}}^2, \sigma_{Z_{l-1}}^2, \sigma_{Z_{l-1}}^2 \right) \leq \frac{1}{n} \sum_{i=1}^{L} \min_{d_1(1, \ldots, L) \geq 2, \ldots, L-1} \phi \left( d_1(1, \ldots, L), d_i(1, \ldots, L), \sigma_{Z_{l-1}}^2, \sigma_{Z_{l-1}}^2, \sigma_{Z_{l-1}}^2, \sigma_{Z_{l-1}}^2 \right).
\]

Define a new function \( \psi(\cdot) \) via the following equation:

\[
\psi \left( d_1(1, \ldots, L), d_i(1, \ldots, L), \sigma_{Z_{l-1}}^2, \sigma_{Z_{l-1}}^2 \right) = \phi \left( d_1(1, \ldots, L), d_i(1, \ldots, L), \sigma_{Z_{l-1}}^2, \sigma_{Z_{l-1}}^2 \right)
\]

where \( \sigma_j^2 = \frac{\sigma_{Z_j}^2}{\sigma_{Z_{l-1}}^2 + \sigma_{Z_{l-1}}^2}, j = 1, \ldots, L-1 \). In view of the fact that there exists a one-to-one map between \( \sigma_{Z_j}^2 \in (0, \infty) \) and \( \sigma_j^2 \in (0, \sigma_{Z_{l-1}}^2) \), we have

\[
\frac{1}{n} \sum_{i=1}^{L} \min_{d_1(1, \ldots, L) \geq 2, \ldots, L-1} \phi \left( d_1(1, \ldots, L), d_i(1, \ldots, L), \sigma_{Z_{l-1}}^2, \sigma_{Z_{l-1}}^2 \right) \leq \frac{1}{n} \sum_{i=1}^{L} \min_{d_1(1, \ldots, L) \geq 2, \ldots, L-1} \psi \left( d_1(1, \ldots, L), d_i(1, \ldots, L), \sigma_{Z_{l-1}}^2, \sigma_{Z_{l-1}}^2 \right).
\]

Note that the right-hand side of the above inequality is not affected if we extend the domain of \( \sigma_j^2 \) from \( (0, \sigma_{Z_{l-1}}^2) \) to \( [0, \sigma_{Z_{l-1}}^2] \). The proof is complete.

### IV. Upper Bound: Proof of Theorem 2

We shall show that for any \( (d_{12}, \ldots, d_{1,1,L-1}) \) with \( d_{1,1,L} \in [0, d_{1,1,L}], i = 2, \ldots, L-1 \),

\[
\kappa \left( d_{11}, \ldots, d_{1L}, d_{12}, \ldots, d_{1,1,L-1}, d_{1,1,L} \right) \leq \max_{\sigma_j^2 \in [0, \sigma_{Z_{l-1}}^2], j = 1, \ldots, L-1} \psi \left( d_{11}, \ldots, d_{1L}, d_{12}, \ldots, d_{1,1,L-1}, \sigma_{Z_{l-1}}^2, \sigma_{Z_{l-1}}^2 \right),
\]

from which Theorem 2 follows immediately. We assume \( d_{1,1,L} > 0 \) for all \( i = 2, \ldots, L-1 \) since otherwise the right-hand side of the inequality is equal to infinity and (17) is trivially true.

Note that the maximization problem

\[
\max_{\sigma_j^2 \in [0, \sigma_{Z_{l-1}}^2], j = 1, \ldots, L-1} \psi \left( d_{11}, \ldots, d_{1L}, d_{12}, \ldots, d_{1,1,L-1}, \sigma_{Z_{l-1}}^2, \sigma_{Z_{l-1}}^2 \right)
\]

can be decomposed into (18) shown at the top of the following page.

**Lemma 2**: Define

\[
d_{1,i+1} = \left( \frac{1}{d_{1,i}} + \frac{1}{d_{i+1}} - \frac{1}{\sigma_X^2} \right)^{-1},
\]

\[
d_{i,j+1} = d_{ij} + d_{i+1} - \sigma_X^2.
\]
max \[ \sigma_j^2 \in [0, \sigma_X^2] \] \[ \log \left( \frac{\sigma_j^2 \left( \sigma_X^2 d_{1,\ldots,j+1} - d_{1,\ldots,j+1} \sigma_j^2 + \sigma_X^2 \sigma_j^2 \right)}{(\sigma_X^2 d_{1,\ldots,j} - d_{1,\ldots,j}) \sigma_j^2 + \sigma_X^2 \sigma_j^2} \right) \right), \quad j = 1, \ldots, L - 1. \quad (18)

1) If \[ \max \{d_{1,\ldots,j}, d_{j+1}\} < \sigma_j^2, \] then \( d_{1,\ldots,j+1} > d_{1,\ldots,j+1} \) and the maximizers to (18) are given by
\[
\sigma_j^2 = \begin{cases} 0, & d_{1,\ldots,j+1} \geq d_{1,\ldots,j+1} \\ \sigma_j^2, & d_{1,\ldots,j+1} \leq d_{1,\ldots,j+1} \\ \text{otherwise} \end{cases}, \quad j = 1, \ldots, L - 1 \quad (19)
\]

where \( \sigma_j^2 \), given at the bottom of the page, is the unique solution to the following equation:
\[
\left( \frac{\sigma_j^2 \left( \sigma_X^2 d_{1,\ldots,j+1} - d_{1,\ldots,j+1} \sigma_j^2 + \sigma_X^2 \sigma_j^2 \right)}{(\sigma_X^2 d_{1,\ldots,j} - d_{1,\ldots,j}) \sigma_j^2 + \sigma_X^2 \sigma_j^2} \right)^{-1}
+ \frac{\sigma_j^2 \left( \sigma_X^2 d_{1,\ldots,j+1} - d_{1,\ldots,j+1} \sigma_j^2 + \sigma_X^2 \sigma_j^2 \right)}{(\sigma_X^2 d_{1,\ldots,j} - d_{1,\ldots,j}) \sigma_j^2 + \sigma_X^2 \sigma_j^2}^{-1} = \frac{1}{\sigma_j^2}
\]

for \( \sigma_j^2 \in (0, \sigma_X^2) \). The maximizers \( \sigma_j^2, j = 1, \ldots, L - 1 \), given in (19) are monotonically increasing continuous functions of \( d_{1,\ldots,j} \) and monotonically decreasing continuous functions of \( d_{1,\ldots,j+1} \); furthermore, the monotonicity is strict when \( \sigma_j^2 \in (0, \sigma_X^2) \).

2) If \( \max \{d_{1,\ldots,j}, d_{j+1}\} = \sigma_j^2 \), then \( d_{1,\ldots,j+1} = d_{1,\ldots,j+1} = \min \{d_{1,\ldots,j}, d_{j+1}\} \) and the maximizers to (18) are given by (20) shown at the bottom of the page. 

\[ \text{Proof: See Appendix B.} \]

Lemma 3: There exist \( \tilde{d}_{1,i}, \tilde{d}_{i}, i = 1, \ldots, L, \) and \( d_{1,\ldots,i}, i = 2, \ldots, L \), such that
\[ \max_{\sigma_j^2 \in [0, \sigma_X^2], j=1,\ldots,L-1} \psi (\tilde{d}_{1}, \ldots, \tilde{d}_{L}, d_{1,\ldots,2}, \ldots, d_{1,\ldots,L}) \]

Proof: See Appendix C.

In view of Lemma 3, to prove (17), it suffices to show that
\[
\kappa (\tilde{d}_{1}, \ldots, \tilde{d}_{L}, d_{1,\ldots,2}, \ldots, d_{1,\ldots,L}) \leq \psi (\tilde{d}_{1}, \ldots, \tilde{d}_{L}, d_{1,\ldots,2}, \ldots, d_{1,\ldots,L}, \sigma_1^2, \ldots, \sigma_{L-1}^2)
\]

where \( \sigma_j^2, j = 1, \ldots, L - 1 \), are the maximizers to (22).

Now we shall associate
\[ \psi (\tilde{d}_{1}, \ldots, \tilde{d}_{L}, d_{1,\ldots,2}, \ldots, d_{1,\ldots,L}, \sigma_1^2, \ldots, \sigma_{L-1}^2) \]

with a natural extension of the EGC achievable rate region. For any random variables \( U_1, \ldots, U_L \) jointly distributed with the generic source variable \( X \), define
\[ \mathcal{R}(U_1, \ldots, U_L) = \left\{ (R_1, \ldots, R_L) : \sum_{i \in A} R_i \geq \sum_{i \in \mathcal{A}} h(U_i) - h(U_j, j \in A \setminus X, \theta \in \mathcal{A} \subseteq \{1, \ldots, L\} \right\}. \]

Note that \( \mathcal{R}(U_1, \ldots, U_L) \) can be viewed as a generalization of the well-known EGC rate region for the 2-description case.

It is observed in [7, 9] that \( \mathcal{R}(U_1, \ldots, U_L) \) has an interesting contra-polymatroid structure; as a consequence, its vertices and supporting hyperplanes can be easily characterized [11]. Specifically, \( (R_1(\pi), \ldots, R_L(\pi)) \) is a vertex of \( \mathcal{R}(U_1, \ldots, U_L) \) for every permutation \( \pi \) on \( \{1, \ldots, L\} \), where
\[ R_{\pi(1)}(\pi) = I(X; U_{\pi(1)}), \]
\[ R_{\pi(i)}(\pi) = I(X, U_{\pi(1)}, \ldots, U_{\pi(i-1)}; U_{\pi(i)}), \quad i = 2, \ldots, L. \]

Moreover, for any nonnegative numbers \( \lambda_1, \ldots, \lambda_L \)
\[ \min_{(R_1, \ldots, R_L) \in \mathcal{R}(U_1, \ldots, U_L)} \sum_{i=1}^L \lambda_i R_i = \sum_{i=1}^L \lambda_{\pi(i)} R_{\pi(i)}(\pi) \]

such that \( \pi \) is any permutation on \( \{1, \ldots, L\} \) such that \( \lambda_{\pi(1)} \geq \cdots \geq \lambda_{\pi(L)} \).

\[ \sigma_j^2 = \sqrt{\left( \frac{\sigma_j^2 \left( \sigma_X^2 d_{1,\ldots,j} - d_{1,\ldots,j} \sigma_j^2 + \sigma_X^2 \sigma_j^2 \right)}{(\sigma_X^2 d_{1,\ldots,j} - d_{1,\ldots,j}) \sigma_j^2 + \sigma_X^2 \sigma_j^2} \right) \left( \frac{\sigma_j^2 \left( \sigma_X^2 d_{1,\ldots,j+1} - d_{1,\ldots,j+1} \sigma_j^2 + \sigma_X^2 \sigma_j^2 \right)}{(\sigma_X^2 d_{1,\ldots,j} - d_{1,\ldots,j}) \sigma_j^2 + \sigma_X^2 \sigma_j^2} \right) \left( \frac{\sigma_j^2 \left( \sigma_X^2 d_{1,\ldots,j} - d_{1,\ldots,j} \sigma_j^2 + \sigma_X^2 \sigma_j^2 \right)}{(\sigma_X^2 d_{1,\ldots,j+1} - d_{1,\ldots,j+1}) \sigma_j^2 + \sigma_X^2 \sigma_j^2} \right) \left( \frac{\sigma_j^2 \left( \sigma_X^2 d_{1,\ldots,j+1} - d_{1,\ldots,j+1} \sigma_j^2 + \sigma_X^2 \sigma_j^2 \right)}{(\sigma_X^2 d_{1,\ldots,j+1} - d_{1,\ldots,j+1}) \sigma_j^2 + \sigma_X^2 \sigma_j^2} \right) \right), \quad j = 1, \ldots, L - 1. \quad (20) \]
Since it is assumed that \(\alpha_1 \geq \cdots \geq \alpha_L > 0\), we have
\[
\min_{(R_1, \ldots, R_L) \in \mathcal{R}(U_1, \ldots, U_L)} \sum_{i=1}^{L} \alpha_i R_i
\]
\[
= \alpha_1 I(X; U_1) + \sum_{i=2}^{L} \alpha_i I(X; U_1, \ldots, U_{i-1}; U_i)
\]
\[
= (\alpha_1 - \alpha_2) I(X; U_1)
\]
\[
+ \sum_{i=2}^{L} (\alpha_i - \alpha_{i+1}) \left( I(X; U_1, \ldots, U_{i-1}; U_i) + \sum_{j=1}^{i-1} I(X; U_1, \ldots, U_{j-1}; U_j) \right)
\]
\[
+ \sum_{i=2}^{L} (\alpha_i - \alpha_{i+1}) I(X; U_1, \ldots, U_{i-1}; U_i).
\]  \hspace{1cm} \text{(23)}

where \(\alpha_{L+1} \triangleq 0\). Note that
\[
I(X; U_1) + \sum_{j=1}^{i-1} I(X; U_1, \ldots, U_j; U_{j+1})
\]
\[
= I(X; U_1) + \sum_{j=1}^{i-1} I(U_1, \ldots, U_j; U_{j+1})
\]
\[
+ I(X; U_{j+1}|U_1, \ldots, U_j)
\]
\[
= I(X; U_1, \ldots, U_i) + \sum_{j=1}^{i-1} I(U_1, \ldots, U_j; U_{j+1}).
\]  \hspace{1cm} \text{(24)}

Substituting (24) into (23), we obtain
\[
\min_{(R_1, \ldots, R_L) \in \mathcal{R}(U_1, \ldots, U_L)} \sum_{i=1}^{L} \alpha_i R_i
\]
\[
= (\alpha_1 - \alpha_2) I(X; U_1) + \sum_{i=2}^{L} (\alpha_i - \alpha_{i+1})
\]
\[
\times \left( I(X; U_1, \ldots, U_i) + \sum_{j=1}^{i-1} I(U_1, \ldots, U_j; U_{j+1}) \right)
\]
\[
= \sum_{i=1}^{L-1} \left((\alpha_i - \alpha_{i+1}) I(X; U_1, \ldots, U_i)
\]
\[
+ \alpha_{i+1} I(U_1, \ldots, U_i; U_{i+1}) + \alpha Li(X; U_1, \ldots, U_L). \right)
\]  \hspace{1cm} \text{(25)}

It can be readily shown (cf. [2]) that
\[
\kappa(\hat{d}_{1}, \ldots, \hat{d}_{L}, \hat{d}_{1,2}, \ldots, \hat{d}_{1,\cdots, L})
\]
\[
\geq \min_{(R_1, \ldots, R_L) \in \mathcal{R}(U_1, \ldots, U_L)} \sum_{i=1}^{L} \alpha_i R_i
\]
for \((U_1, \ldots, U_L)\) with
\[
\text{cov}(X | U_i) \leq \hat{d}_{(i)}, \quad i = 1, \ldots, L
\]  \hspace{1cm} \text{(26)}
\[
\text{cov}(X | U_1, \ldots, U_i) \leq \hat{d}_{(1,\cdots,i)}, \quad i = 2, \ldots, L
\]  \hspace{1cm} \text{(27)}

Therefore, to complete the proof, it suffices to construct \((U_1, \ldots, U_L)\) satisfying (26) and (27) such that
\[
\min_{(R_1, \ldots, R_L) \in \mathcal{R}(U_1, \ldots, U_L)} \sum_{i=1}^{L} \alpha_i R_i = \psi \left( \hat{d}_{(1)}, \ldots, \hat{d}_{(L)}, \hat{d}_{(1,2)}, \ldots, \hat{d}_{(1,\cdots,L)}, \hat{\sigma}_2^2, \ldots, \hat{\sigma}_L^2 \right).
\]  \hspace{1cm} \text{(28)}

It is easy to verify the following lemma, which will be served as a building block for constructing the desired covariance matrix of \((U_1, \ldots, U_L)\).

**Lemma 4:** For any \(d_0, d_1, d_2 \in (0, \sigma^2_X)\) satisfying
\[
d_1 + d_2 - \sigma^2_X \leq d_0 \leq \left( \frac{1}{d_1} + \frac{1}{d_2} - \frac{1}{\sigma^2_X} \right)^{-1}
\]
define
\[
V_1 = X + N' + \sqrt{\frac{\sigma^2_X d_1}{\sigma^2_X - d_1} - \frac{\sigma^2_X d_0}{\sigma^2_X - d_0}} N',
\]
\[
V_2 = X + N' - \sqrt{\frac{\sigma^2_X d_2}{\sigma^2_X - d_2} - \frac{\sigma^2_X d_0}{\sigma^2_X - d_0}} N',
\]
where \(N \sim \mathcal{N}(0, \sigma^2_X), N' \sim \mathcal{N}(0, 1),\) and \(X \sim \mathcal{N}(0, \sigma^2_X)\) are independent. We have
\[
\text{cov}(X | V_i) = d_i, \quad i = 1, 2,
\]
\[
\text{cov}(X | V_1, V_2) = \text{cov}(X | X + N') = d_0,
\]
\[
\text{E}(V_1 V_2) \in [0, \sigma^2_X].
\]

**Remark:**
1) Given \(V_1\) and \(V_2\), one can construct \(X + N\).
2) Write \(X = \hat{X} + \tilde{X}\), where \(\hat{X} \sim \mathcal{N}(0, \sigma^2_X - \sigma^2)\) and \(\tilde{X} \sim \mathcal{N}(0, \sigma^2)\) are independent, and
\[
\sigma^2 = \sqrt{\left( \frac{\sigma^2_X d_1}{\sigma^2_X - d_1} - \frac{\sigma^2_X d_0}{\sigma^2_X - d_0} \right) \left( \frac{\sigma^2_X d_2}{\sigma^2_X - d_2} - \frac{\sigma^2_X d_0}{\sigma^2_X - d_0} \right) - \frac{\sigma^2_X d_0}{\sigma^2_X - d_0}}.
\]

Note that \(V_1\) and \(V_2\) are independent conditioned on \(\hat{X}\) since
\[
\text{E} \left( (X + N' + \sqrt{\frac{\sigma^2_X d_1}{\sigma^2_X - d_1} - \frac{\sigma^2_X d_0}{\sigma^2_X - d_0}} N') (X + N' - \sqrt{\frac{\sigma^2_X d_2}{\sigma^2_X - d_2} - \frac{\sigma^2_X d_0}{\sigma^2_X - d_0}} N') \right) = 0.
\]

Therefore, we have
\[
I(V_1, V_2) = I(\hat{X}; V_1) + I(\hat{X}; V_2) + I(V_1, V_2 | \hat{X})
\]
\[
- I(\hat{X}; V_1, V_2)
\]
\[
= I(\tilde{X}; V_1) + I(\tilde{X}; V_2) - I(\hat{X}; V_1, V_2)\]
\[ I(\hat{X}; V_1) + I(\hat{X}; V_2) - I(\hat{X}; X + N) \]
\[ = \frac{1}{2} \log \left( \frac{\sigma_X^2 \left( \sigma_X^2 d_0 - d_0 \sigma_X^2 + \sigma_Y^2 \sigma_X^2 \right)}{(\sigma_X^2 d_1 - d_1 \sigma_X^2 + \sigma_X^2 \sigma_Y^2)(\sigma_Y^2 d_2 - d_2 \sigma_Y^2 + \sigma_Y^2 \sigma_X^2)} \right). \]

Now we proceed to give an explicit construction of \((U_1, \ldots, U_L)\). First consider the case where \(d_{\{i\}} < \sigma_X^2\) for all \(i = 1, \ldots, L\), which, by (21), further implies \(d_{\{1, \ldots, i\}} < \sigma_X^2\) for all \(i = 2, \ldots, L\). In view of (21) and Lemma 2, we have the first equation shown at the bottom of the page.

By Lemma 4, we can construct
\[ U_1 = X + N_{\{1,2\}} + \frac{\sigma_X^2 d_{\{1,2\}}}{\sigma_X^2 - d_{\{1,2\}}} N_{\{1,2\}}, \]
\[ U_2 = X + N_{\{1,2\}} - \frac{\sigma_X^2 d_{\{2\}}}{\sigma_X^2 - d_{\{2\}}} N_{\{1,2\}}, \]
where \(N_{\{1,2\}} \sim \mathcal{N}(0, \sigma_X^2 d_{\{1,2\}}^{-1})\), \(N_{\{1,2\}} \sim \mathcal{N}(0, 1)\), and \(X \sim \mathcal{N}(0, \sigma_X^2)\) are mutually independent. Now we write
\[ N_{\{1,2\}} = N_{\{1,2,3\}} + \frac{\sigma_X^2 d_{\{2,3\}}}{\sigma_X^2 - d_{\{2,3\}}} \sqrt{\frac{\sigma_X^2 d_{\{1\}}}{\sigma_X^2 - d_{\{1\}}}} N_{\{1,2,3\}}', \]
where \(N_{\{1,2,3\}} \sim \mathcal{N}(0, \sigma_X^2 d_{\{1,2,3\}}^{-1})\) and \(N_{\{1,2,3\}}' \sim \mathcal{N}(0, 1)\) are mutually independent. Again, by Lemma 4, we can construct
\[ U_3 = X + N_{\{1,2,3\}} - \frac{\sigma_X^2 d_{\{3\}}}{\sigma_X^2 - d_{\{3\}}} \frac{\sigma_X^2 d_{\{2,3\}}}{\sigma_X^2 - d_{\{2,3\}}} N_{\{1,2,3\}}, \]
Now we can further write
\[ N_{\{1,2,3\}} = N_{\{1,2,3,4\}} \]

\[ \theta^2 = \sqrt{\left( \frac{\sigma_X^2 d_{\{1,\ldots,j-1\}} - \sigma_X^2 d_{\{1,\ldots,j+1\}}}{\sigma_X^2 - d_{\{1,\ldots,j\}}} \frac{\sigma_X^2 d_{\{j+1\}} - \sigma_X^2 d_{\{1,\ldots,j+1\}}}{\sigma_X^2 - d_{\{j+1\}}} \right) \left( \frac{\sigma_X^2 d_{\{1,\ldots,j\}} - \sigma_X^2 d_{\{1,\ldots,j+1\}}}{\sigma_X^2 - d_{\{1,\ldots,j\}}} \frac{\sigma_X^2 d_{\{j+1\}} - \sigma_X^2 d_{\{1,\ldots,j+1\}}}{\sigma_X^2 - d_{\{j+1\}}} \right)} \]
\[ \frac{\sigma_X^2 d_{\{j+1\}} - \sigma_X^2 d_{\{1,\ldots,j+1\}}}{\sigma_X^2 - d_{\{j+1\}}} \right)}, \]

\[ j = 1, \ldots, L - 1. \]

\[ I(X; U_1) = \frac{1}{2} \log \left( \frac{\sigma_X^2}{d_{\{1\}}} \right) \]
\[ I(X; U_1, \ldots, U_i) = I(X; X + N_{\{1,\ldots,i\}}) \]
\[ I(U_1; U_2) = \frac{1}{2} \log \left( \frac{\sigma_X^2}{d_{\{1\}}} \left( \sigma_X^2 d_{\{1,2\}} - d_{\{1\}} \sigma_X^2 + \sigma_Y^2 \sigma_X^2 \right) \right) \]
\[ I(U_1, \ldots, U_{i-1}; U_i) = I(X + N_{\{1,\ldots,i-1\}}; U_i) \]
\[ = \frac{1}{2} \log \left( \frac{\sigma_X^2}{d_{\{i\}}} \left( \sigma_X^2 d_{\{i,\ldots,i-1\}} - d_{\{i,\ldots,i-1\}} \sigma_Y^2 + \sigma_X^2 \sigma_Y^2 \right) \right), \]
\[ i = 2, \ldots, L. \]
can be decomposed into
\[
\begin{align*}
\min_{d_{(1,\cdots,i)} \in \{0,d'_{(1,\cdots,i)}\}} & \frac{\alpha_i}{2} \log \left( \frac{\sigma_i^2 d_{(1,\cdots,i)}^2}{\sigma_i^2 d_{(1,\cdots,i)}^2 + \sigma_i^2 \sigma_{i+1}^2} \right) + \frac{\alpha_{i+1}}{2} \log(d_{(1,\cdots,i+1)}) \\
& - \frac{\alpha_i - \alpha_{i+1}}{2} \log(d_{(1,\cdots,i)}) \\
& - \frac{\alpha_{i+1}}{2} \log \left( \frac{\sigma_i^2 d_{(1,\cdots,i)}^2}{\sigma_i^2 d_{(1,\cdots,i)}^2 + \sigma_i^2 \sigma_{i+1}^2} \right), \\
& \quad i = 2, \ldots, L - 1.
\end{align*}
\]  
(33)

Lemma 5: If \(\alpha_i > \alpha_{i+1}\), then the minimizers to (33) are given by (34) shown at the bottom of the page, where
\[
d_{(1,\cdots,i)} = \frac{(\alpha_i - \alpha_{i+1}) \sigma_i^2 \sigma_{i+1}^2}{\alpha_i \sigma_i^2 - \alpha_{i+1} \sigma_{i+1}^2}.
\]
If \(\alpha_i = \alpha_{i+1}\), then the minimizers to (33) are given by
\[
d_{(1,\cdots,i)} = \begin{cases} 
0, & \sigma_{i+1}^2 > \sigma_i^2 \\
\text{any number in } [0,d'_{(1,\cdots,i)}], & \sigma_{i+1}^2 \leq \sigma_i^2 
\end{cases}, \quad i = 2, \ldots, L - 1.
\]
(35)

Proof: See Appendix D.

First consider the case where individual distortion constraints \(d_{(i)}, i = 2, \ldots, L\), auxiliary distortion constraints \(d'_{(1,\cdots,i)}, i = 2, \ldots, L - 1\), and central distortion constraint \(d_{(1,\cdots,L)}\) are all less than \(\sigma_i^2\).

Let \((\hat{d}_{(1,2)}, \ldots, \hat{d}_{(1,\cdots,L-1)}, \sigma_{1}^2, \ldots, \sigma_{L-1}^2)\) be a solution to the min-max game in (4). We shall show that \((\hat{d}_{(1,2)}, \ldots, \hat{d}_{(1,\cdots,L-1)}, \sigma_{1}^2, \ldots, \sigma_{L-1}^2)\) must satisfy the saddle point conditions (19) and (34) or (35).

Note that (19) is automatically satisfied. Suppose (34) or (35) is violated by some \(\hat{d}_{(1,\cdots,i)}\). We shall focus on \(\hat{d}_{(1,\cdots,i)}\), \(\sigma_{i+1}^2\), and \(\sigma_i^2\) while assuming everything else is fixed. Since \(\sigma_{i+1}^2\) and \(\sigma_i^2\) are determined by \(\hat{d}_{(1,\cdots,i)}\) according to (19), to stress this dependence, we denote \(\sigma_{i+1}^2\) and \(\sigma_i^2\) as \(\sigma_{i+1}^2(d_{(1,\cdots,i)})\) and \(\sigma_i^2(d_{(1,\cdots,i)})\), respectively. By Lemma 2, \(\sigma_{i+1}^2\) is a monotonically decreasing continuous function of \(d_{(1,\cdots,i)}\) while \(\sigma_i^2(d_{(1,\cdots,i)})\) is a monotonically increasing continuous function of \(d_{(1,\cdots,i)}\). Define
\[
\eta(d_{(1,\cdots,i)}) = \frac{\alpha_{i+1}}{2} \log \left( \frac{\sigma_i^2 d_{(1,\cdots,i)}^2}{\sigma_i^2 d_{(1,\cdots,i)}^2 + \sigma_i^2 \sigma_{i+1}^2} \right) - \frac{\alpha_i - \alpha_{i+1}}{2} \log(d_{(1,\cdots,i)}) - \frac{\alpha_{i+1}}{2} \log \left( \frac{\sigma_i^2 d_{(1,\cdots,i)}^2}{\sigma_i^2 d_{(1,\cdots,i)}^2 + \sigma_i^2 \sigma_{i+1}^2} \right) + \frac{\alpha_i}{2} \log \left( \frac{\sigma_i^2 d_{(1,\cdots,i)}^2}{\sigma_i^2 d_{(1,\cdots,i)}^2 + \sigma_i^2 \sigma_{i+1}^2} \right).
\]

Note that \(\eta(d_{(1,\cdots,i)})\) is a monotonically increasing continuous function of \(d_{(1,\cdots,i)}\). Now consider the following cases.

1. Case 1: \(\alpha_i > \alpha_{i+1}\), \(d_{(1,\cdots,i)} < d'_{(1,\cdots,i)}\), and \(\eta(d_{(1,\cdots,i)}) \leq 0\). Increase \(d_{(1,\cdots,i)}\) from \(d_{(1,\cdots,i)}\) until one of the following happens: \(d_{(1,\cdots,i)} = d'_{(1,\cdots,i)}\) or \(\eta(d_{(1,\cdots,i)}) = 0\). If we first have \(d_{(1,\cdots,i)} = d'_{(1,\cdots,i)}\), then set \(d_{(1,\cdots,i+1)} = d_{(1,\cdots,i)}\). Now suppose we first have \(\eta(d_{(1,\cdots,i)}) = 0\). Denote the corresponding \(d_{(1,\cdots,i)}\) by \(d_{(1,\cdots,i)}^*\). It can be seen that only the following three situations are possible:
   a) \(\sigma_{i+1}^2(d_{(1,\cdots,i)}) = \sigma_i^2(d_{(1,\cdots,i)}) = \sigma_i^2\),
   b) \(\sigma_i^2(d_{(1,\cdots,i)}) = \sigma_{i+1}^2(d_{(1,\cdots,i)}) = \sigma_i^2\),
   c) \(\sigma_i^2(d_{(1,\cdots,i)}) \in (0, \sigma_i^2)\) and \(\sigma_{i+1}^2(d_{(1,\cdots,i)}^*) \in (0, \sigma_i^2)\).

For situation a), we set \(d_{(1,\cdots,i+1)}^* = \sigma_i^2\). For situation b), we further increase \(d_{(1,\cdots,i)}\) until one of the following happens: \(d_{(1,\cdots,i)} = d'_{(1,\cdots,i)}\) or \(\eta(d_{(1,\cdots,i)})\) becomes positive. If \(d_{(1,\cdots,i)} = d'_{(1,\cdots,i)}\) happens first, then set \(d_{(1,\cdots,i+1)} = d_{(1,\cdots,i)}\). If \(\eta(d_{(1,\cdots,i)})\) becomes positive, then we further increase \(d_{(1,\cdots,i)}\) until it meets \(\min\{\hat{d}_{(1,\cdots,i)}, d_{(1,\cdots,i)}\}\) and then set \(d_{(1,\cdots,i+1)}^* = \sigma_i^2\). For situation c), \(\eta(d_{(1,\cdots,i)})\) is at the point of turning positive (cf. Lemma 2). We can further increase \(d_{(1,\cdots,i)}\) until it meets \(\min\{\hat{d}_{(1,\cdots,i)}, d_{(1,\cdots,i)}\}\) and then set \(d_{(1,\cdots,i+1)}^* = \sigma_i^2\) to be equal to the corresponding \(d_{(1,\cdots,i)}\). For situation b), \(\eta(d_{(1,\cdots,i)})\) is a monotonically increasing continuous function of \(d_{(1,\cdots,i)}\) and \(\sigma_i^2(d_{(1,\cdots,i)}^*)\), and it is a monotonically decreasing continuous function of \(\sigma_i^2(d_{(1,\cdots,i)}^*)\), thus, is a monotonically decreasing continuous function of \(d_{(1,\cdots,i)}\). Furthermore, we have \(d_{(1,\cdots,i+1)} = \sigma_i^2\) at the point where \(\eta(d_{(1,\cdots,i)})\) turns positive. Therefore, the above procedure is always possible.

2. Case 2: \(\alpha_i > \alpha_{i+1}\), \(d_{(1,\cdots,i)} < d_{(1,\cdots,i)}^*\), and \(\eta(d_{(1,\cdots,i)}) < 0\). We can increase \(d_{(1,\cdots,i)}\) from \(d_{(1,\cdots,i)}\) until it hits \(\min\{d_{(1,\cdots,i)}, d_{(1,\cdots,i)}^*\}\) and then set \(d_{(1,\cdots,i+1)}^* = \sigma_i^2\). Note that both

\[
d_{(1,\cdots,i)} = \begin{cases} 
\alpha_i^2 d_{(1,\cdots,i)}^2, & \quad \alpha_i > \alpha_{i+1}, \\
\eta(d_{(1,\cdots,i)}), & \quad \alpha_i = \alpha_{i+1}, \\
\alpha_i^2 d_{(1,\cdots,i)}^2, & \quad \alpha_i < \alpha_{i+1}, \\
\text{any number in } [0,d'_{(1,\cdots,i)}], & \quad \sigma_{i+1}^2 > \sigma_i^2, \\
\text{any number in } (0,d'_{(1,\cdots,i)}], & \quad \sigma_{i+1}^2 = \sigma_i^2. 
\end{cases}
\]
(34)
\[ \sigma^2_{c-1}(d^1_{1,...,i}) \text{ and } \sigma^2_{c}(d^1_{1,...,i}) \text{ must be equal to zero.} \]

4) Case 4: \( \alpha_{c} = \alpha_{c+1} \), \( d^1_{1,...,i} < d^1_{1,...,i} \), and \( \sigma^2_{c-1}(d^1_{1,...,i}) > \sigma^2_{c}(d^1_{1,...,i}) \). Increase \( d^1_{1,...,i} \) from \( d^1_{1,...,i} \) until one of the following happens: \( d^1_{1,...,i} = d^1_{1,...,i} \) or \( \sigma^2_{c-1}(d^1_{1,...,i}) = \sigma^2_{c}(d^1_{1,...,i}) \). Set \( d^*_{c}(d^1_{1,...,i}) \) to be equal to the corresponding \( d^1_{1,...,i} \).

5) Case 5: \( \alpha_{c} = \alpha_{c+1} > 0 \), and \( \sigma^2_{c-1}(d^1_{1,...,i}) < \sigma^2_{c}(d^1_{1,...,i}) \). Decrease \( d^1_{1,...,i} \) from \( d^1_{1,...,i} \) until \( \sigma^2_{c-1}(d^1_{1,...,i}) = \sigma^2_{c}(d^1_{1,...,i}) \) and then set \( d^*_{c}(d^1_{1,...,i}) \) to be equal to the corresponding \( d^1_{1,...,i} \).

Through the above construction, the resulting \( d^*_{i}(d^1_{1,...,i}), \sigma^2_{c}(d^1_{1,...,i}) \), and \( \sigma^2_{c-1}(d^1_{1,...,i}) \) must satisfy (34) (or (35)). Note that

\[
\psi(d_{1},...,d_{L},d_{1,2},...,d_{1,...,L-1},d_{1,...,i}) = \max_{\psi(d_{1},...,d_{L},d_{1,2},...,d_{1,...,L-1})} \psi(d_{1},...,d_{L},d_{1,2},...,d_{1,...,L-1}) \geq \psi(d_{1},...,d_{L},d_{1,2},...,d_{1,...,L-1}) \geq \psi(d_{1},...,d_{L},d_{1,2},...,d_{1,...,L-1}) = \psi(d_{1},...,d_{L},d_{1,2},...,d_{1,...,L-1}) = \psi(d_{1},...,d_{L},d_{1,2},...,d_{1,...,L-1})
\]

Therefore, \( d^*_{i}(d^1_{1,...,i}), \sigma^2_{c}(d^1_{1,...,i}) \), and \( \sigma^2_{c-1}(d^1_{1,...,i}) \) satisfy (34) (or (35)), which leads a contradiction with the assumption that (34) (or (35)) is violated. As a consequence, \( d^*_{1},...,d^*_{1,...,L-1},d^*_{1},...,d^*_{1,...,L-1} \) must be a saddle point.

Now we proceed to treat the case where some of the distortion constraints are equal to \( \sigma^2_{c} \) using a limiting argument. We subtract each distortion constraint by \( \epsilon \). It is clear that the resulting distortion constraints are all less than \( \sigma^2_{c} \); therefore, the above described argument can be used to prove the existence of a saddle point. By sending \( \epsilon \) to zero, one can find a converging subsequence of saddle points. It can be readily verified that the limiting value is a saddle point of the original max-min/min-max game. This completes the proof of Theorem 3.

A detailed characterization of the saddle point can be found in Appendix E.

VI. CONCLUSION

We have characterized the rate region of Gaussian multiple description coding with individual and central distortion constraints. Different from the 2-description case and the minimum sum-rate case where a single auxiliary random vector suffices to yield a matching converse, multiple auxiliary random vectors \( Z^1_n, \ldots, Z^L_n \) are needed in the current setting. Note that although it is not necessary to specify the joint distribution of \( Z^1_n, \ldots, Z^L_n \) in our proof, one may put them into the same probability space and create a certain structure. In particular, if only individual and central distortion constraints are imposed, the auxiliary random vectors \( Z^1_n, \ldots, Z^L_n \) can be arranged to form a Markov chain with an order determined by \( \alpha_1, \ldots, \alpha_L \); however, this order can be affected if additional distortion constraints are introduced. It is worth noting that Markov structured auxiliary random vectors have also been used in a recent work [12] to derive an outer bound of the Gaussian multiple description problem with symmetric distortion constraints that is within a constant gap from the inner bounds. Our result indicates that in the case where only individual and central distortion constraints are imposed, one can in fact obtain the true rate region by systematically optimizing the auxiliary random vectors.

APPENDIX A

PROOF OF LEMMA 1

Consider the following two cases.

1) Case 1: \( \sigma^2_{c} > \sigma^2_{c} \). We can write \( N^c_n = N^c_n + \tilde{N}^n \), where \( \tilde{N}^n \) is an \( n \)-dimensional Gaussian random vector with covariance matrix \( (\sigma^2_{c} - \sigma^2_{c}) I_n \), and \( \tilde{N}^n \) is independent of \( N^c_n \). Note that

\[
\mu_1 h(S^n + N^c_n | T) + \mu_2 h(S^n + N^c_n | T) = \mu_1 h(S^n | N^c_n | T) - \mu_1 h(S^n + N^c_n + \tilde{N}^n | T) - (\mu_2 - \mu_1) h(S^n + N^c_n + \tilde{N}^n | T) + (\mu_2 - \mu_1) h(S^n | T)
\]
Define $\hat{S}^n = \mathbb{E}(S^n | T)$. We have

$$I(\hat{N}^n; S^n + N_1^n + \hat{N}^n | T)$$

$$= h(\hat{N}^n) - h(S^n + N_1^n + \hat{N}^n, T)$$

$$\geq h(\hat{N}^n) - h(S^n + \hat{N}^n, T)$$

$$= \sum_{m=1}^n \left( h(\hat{N}(m)) - h(\hat{N}(m) | S(m)
- \hat{S}(m) + N_1(m) + \hat{N}(m)) \right)$$

$$= \sum_{m=1}^n I(\hat{N}(m); S(m) - \hat{S}(m) + N_1(m) + \hat{N}(m))$$

$$\geq \frac{1}{2} \log \left( \frac{\mathbb{E}(S(m) - \hat{S}(m))^2 + \sigma_1^2}{\mathbb{E}(S(m) - \hat{S}(m))^2 + \sigma_1^2} \right)$$

$$\geq \frac{1}{2} \log \left( \frac{d' + \sigma_1^2}{d' + \sigma_2^2} \right)$$

(38)

where (38) follows from the worst additive noise lemma [13, Lemma II.2], and (39) follows from the convexity and monotonicity of $\log(a + b)$ in $b$ (when $a > 0$ and $b \geq 0$) as well as the fact that $tr(\text{cov}(S^n | T)) \leq nd$. Similarly, it can be shown that

$$I(N_i^n; S^n + N_2^n | T) \geq \frac{n}{2} \log \left( \frac{d' + \sigma_i^2}{d' + \sigma_2^2} \right), \quad i = 1, 2.$$  

(40)

In view of the fact that both $\mu_1$ and $\mu_2 - \mu_1$ are nonnegative, we have

$$\mu_1 h(S^n + N_1^n | T) - \mu_2 h(S^n + N_2^n | T)$$

$$+ (\mu_2 - \mu_1) h(S^n | T)$$

$$\leq \frac{\mu_1 n}{2} \log \left( \frac{d' + \sigma_1^2}{d' + \sigma_2^2} \right)$$

$$+ \frac{(\mu_2 - \mu_1) n}{2} \log(d' + \sigma_2^2)$$

$$\leq \frac{\mu_1 n}{2} \log(d' + \sigma_1^2) - \frac{\mu_2 - \mu_1) n}{2} \log(d' + \sigma_2^2)$$

$$+ \frac{(\mu_2 - \mu_1) n}{2} \log(d).$$

(41)

2) Case 2: $\sigma_2^2 \leq \sigma_1^2$. By the conditional version of Costa’s entropy power inequality [10] (cf. [14]), we have

$$h(S^n + N_2^n | T)$$

$$= h \left( S^n + \sqrt{\frac{\sigma_2^2}{\sigma_1^2}} N_1^n | T \right)$$

$$\geq \frac{n}{2} \log \left( 1 - \frac{\sigma_2^2}{\sigma_1^2} \exp \left( \frac{2}{n} h(S^n | T) \right) \right.$$ \n
$$+ \frac{\sigma_2^2}{\sigma_1^2} \exp \left( \frac{2}{n} h(S^n + N_1^n | T) \right) \Big).$$

Therefore

$$\mu_1 h(S^n + N_1^n | T) - \mu_2 h(S^n + N_2^n | T)$$

$$+ (\mu_2 - \mu_1) h(S^n | T)$$

$$\leq \mu_1 h(S^n + N_1^n | T) - \frac{\mu_2 n}{2} \log \left( \frac{1 - \frac{\sigma_2^2}{\sigma_1^2} \exp \left( \frac{2}{n} h(S^n | T) \right) + \frac{\sigma_2^2}{\sigma_1^2} \exp \left( \frac{2}{n} h(S^n + N_1^n | T) \right)}{\frac{\sigma_1^2}{\sigma_1^2} + \frac{\sigma_2^2}{\sigma_2^2}} \right)$$

$$+ \left( \frac{\mu_2 - \mu_1) n}{2} \log \left( \frac{1 - \frac{\sigma_2^2}{\sigma_1^2} \exp \left( \frac{2}{n} h(S^n + N_1^n | T) \right)}{\frac{\sigma_1^2}{\sigma_1^2} + \frac{\sigma_2^2}{\sigma_2^2}} \right) \right).$$

Now it follows from (40) that

$$\mu_1 h(S^n + N_1^n | T) - \mu_2 h(S^n + N_2^n | T)$$

$$+ (\mu_2 - \mu_1) h(S^n | T)$$

$$\leq \max_{d \in [0, d'] \frac{\mu_1 n}{2} \log \left( \frac{d + \sigma_2^2}{d} \right)$$

$$+ \frac{(\mu_2 - \mu_1) n}{2} \log \left( \frac{d + \sigma_2^2}{d + \sigma_1^2} \right)$$

$$= \max_{d \in [0, d'] \frac{\mu_1 n}{2} \log \left( d + \sigma_2^2 \right) + \frac{(\mu_2 - \mu_1) n}{2} \log(d),$$

The proof is complete.

APPENDIX B

PROOF OF LEMMA 2

We shall only treat the case $max\{d_1, \ldots, d_{j+1}\} < \sigma_2^2$ since the other one is straightforward to verify. Consider the objective function $G_j(\sigma_2^2)$ shown in the equation at the bottom of the page. It is easy to verify that

$$\frac{\partial G_j(\sigma_2^2)}{\partial \sigma_2^2} = \left( \frac{\sigma_2^2 d_{1, \ldots, j+1} - \sigma_1^2 d_{1, \ldots, j} + \sigma_j^2}{\sigma_2^2 d_{1, \ldots, j+1} - \sigma_1^2 d_{1, \ldots, j} + \sigma_2^2} \right)^{-1}$$

$$- \left( \frac{\sigma_2^2 d_{1, \ldots, j+1} - \sigma_1^2 d_{1, \ldots, j} + \sigma_j^2}{\sigma_2^2 d_{1, \ldots, j+1} - \sigma_1^2 d_{1, \ldots, j} + \sigma_2^2} \right)^{-1}$$

$$- \left( \frac{\sigma_2^2 d_{1, \ldots, j+1} - \sigma_1^2 d_{1, \ldots, j} + \sigma_j^2}{\sigma_2^2 d_{1, \ldots, j+1} - \sigma_1^2 d_{1, \ldots, j} + \sigma_2^2} \right)^{-1}$$

$$- \left( \frac{\sigma_2^2 d_{1, \ldots, j+1} - \sigma_1^2 d_{1, \ldots, j} + \sigma_j^2}{\sigma_2^2 d_{1, \ldots, j+1} - \sigma_1^2 d_{1, \ldots, j} + \sigma_2^2} \right)^{-1}$$

$$\frac{\partial G_j(\sigma_2^2)}{\partial d_{j+1}} = \left( \frac{\sigma_2^2 d_{1, \ldots, j+1} - \sigma_1^2 d_{1, \ldots, j} + \sigma_j^2}{\sigma_2^2 d_{1, \ldots, j+1} - \sigma_1^2 d_{1, \ldots, j} + \sigma_2^2} \right)^{-2}$$

$$+ \left( \frac{\sigma_2^2 d_{1, \ldots, j+1} - \sigma_1^2 d_{1, \ldots, j} + \sigma_j^2}{\sigma_2^2 d_{1, \ldots, j+1} - \sigma_1^2 d_{1, \ldots, j} + \sigma_2^2} \right)^{-2}$$

The optimum $d_{j+1}$ is given by

$$G_j(\sigma_2^2) = \log \left( \frac{\sigma_2^2 d_{1, \ldots, j+1} - \sigma_1^2 d_{1, \ldots, j} + \sigma_j^2}{\sigma_2^2 d_{1, \ldots, j+1} - \sigma_1^2 d_{1, \ldots, j} + \sigma_2^2} \right)^2.$$
such that is a strictly monotonically decreasing for to (in which case is a ).

Therefore, \( G_j(\sigma_j^2) \) is a local maximum for any \( \sigma_j^2 \in [0, \sigma_X^2] \) satisfying \( \frac{\partial G_j(\sigma_j^2)}{\partial \sigma_j^2} |_{\sigma_j^2=\sigma_j^2} = 0 \) and there is no local minimum in \((0, \sigma_X^2)\).

Note that

\[
\frac{\partial G_j(\sigma_j^2)}{\partial \sigma_j^2} |_{\sigma_j^2=0} = \frac{1}{d_{[1,\ldots,j]+1}} + \frac{1}{\sigma_X^2 - d_{[1,\ldots,j]}} - \frac{1}{d_{[j+1]}}.
\]

It is easy to show that

\[
\left( \frac{1}{d_{[1,\ldots,j]}} + \frac{1}{d_{[j+1]} - \sigma_X^2} \right) ^{-1} \geq d_{[1,\ldots,j]} + d_{[j+1]} - \sigma_X^2
\]

with inequality if and only if \( \max\{d_{[1,\ldots,j]}, d_{[j+1]}\} = \sigma_X^2 \).

Therefore, we have

\[
\frac{\partial G_j(\sigma_j^2)}{\partial \sigma_j^2} |_{\sigma_j^2=0} \leq 0 \Rightarrow \frac{\partial G_j(\sigma_j^2)}{\partial \sigma_j^2} |_{\sigma_j^2=\sigma_X^2} \leq 0, \quad (41)
\]

and

\[
\frac{\partial G_j(\sigma_j^2)}{\partial \sigma_j^2} |_{\sigma_j^2=\sigma_X^2} \geq 0 \Rightarrow \frac{\partial G_j(\sigma_j^2)}{\partial \sigma_j^2} |_{\sigma_j^2=0} \geq 0. \quad (42)
\]

In both (41) and (42), if the first inequality is strict, then the second inequality is also strict. Furthermore, \( \frac{\partial G_j(\sigma_j^2)}{\partial \sigma_j^2} |_{\sigma_j^2=0} \leq 0 \) and \( \frac{\partial G_j(\sigma_j^2)}{\partial \sigma_j^2} |_{\sigma_j^2=\sigma_X^2} \geq 0 \) hold simultaneously if and only if one of \( d_{[1,\ldots,j]} \) and \( d_{[j+1]} \) is equal to \( d_{[1,\ldots,j]} \) plus the other is equal to \( \sigma_X^2 \) (in which case \( G_j(\sigma_j^2) \) does not depend on \( \sigma_j^2 \)). Since both \( d_{[1,\ldots,j]} \) and \( d_{[j+1]} \) are less than \( \sigma_X^2 \) under our assumption, only the following three cases need to be considered.

1) Case 1: \( \frac{\partial G_j(\sigma_j^2)}{\partial \sigma_j^2} |_{\sigma_j^2=0} \leq 0 \) and \( \frac{\partial G_j(\sigma_j^2)}{\partial \sigma_j^2} |_{\sigma_j^2=\sigma_X^2} < 0 \).

We have \( \frac{\partial G_j(\sigma_j^2)}{\partial \sigma_j^2} |_{\sigma_j^2=\sigma_X^2} < 0 \) for \( \sigma_j^2 \in (0, \sigma_X^2) \). Otherwise, if \( \frac{\partial G_j(\sigma_j^2)}{\partial \sigma_j^2} |_{\sigma_j^2=\sigma_X^2} = 0 \) for some \( \sigma_j^2 \in (0, \sigma_X^2) \), then \( G_j(\sigma_j^2) \) is a local maximum, and there must exist a local minimum in \((0, \sigma_j^2)\), which leads to a contradiction with the fact that no local minimum exists in \((0, \sigma_X^2)\). Therefore, \( G_j(\sigma_j^2) \) is a strictly decreasing function of \( \sigma_j^2 \) from 0 to \( \sigma_X^2 \).

2) Case 2: \( \frac{\partial G_j(\sigma_j^2)}{\partial \sigma_j^2} |_{\sigma_j^2=\sigma_X^2} \geq 0 \) and \( \frac{\partial G_j(\sigma_j^2)}{\partial \sigma_j^2} |_{\sigma_j^2=0} > 0 \).

We have \( \frac{\partial G_j(\sigma_j^2)}{\partial \sigma_j^2} |_{\sigma_j^2=\sigma_X^2} > 0 \) for \( \sigma_j^2 \in [0, \sigma_X^2) \). Otherwise, if \( \frac{\partial G_j(\sigma_j^2)}{\partial \sigma_j^2} |_{\sigma_j^2=0} = 0 \) for some \( \sigma_j^2 \in (0, \sigma_X^2) \), then \( G_j(\sigma_j^2) \) is a local maximum, and there must exist a local minimum in \((\sigma_j^2, \sigma_X^2)\), which leads to a contradiction. Therefore, \( G_j(\sigma_j^2) \) is a strictly increasing function of \( \sigma_j^2 \) from 0 to \( \sigma_X^2 \).

3) Case 3: \( \frac{\partial G_j(\sigma_j^2)}{\partial \sigma_j^2} |_{\sigma_j^2=0} > 0 \) and \( \frac{\partial G_j(\sigma_j^2)}{\partial \sigma_j^2} |_{\sigma_j^2=\sigma_X^2} < 0 \). There exists a unique \( \sigma_j^2 \in (0, \sigma_X^2) \) satisfying \( \frac{\partial G_j(\sigma_j^2)}{\partial \sigma_j^2} |_{\sigma_j^2=\sigma_j^2} = 0 \). We have \( \frac{\partial G_j(\sigma_j^2)}{\partial \sigma_j^2} |_{\sigma_j^2=\sigma_j^2} > 0 \) for \( \sigma_j^2 \in [0, \sigma_j^2) \), and \( \frac{\partial G_j(\sigma_j^2)}{\partial \sigma_j^2} |_{\sigma_j^2=\sigma_j^2} < 0 \) for \( \sigma_j^2 \in (\sigma_j^2, \sigma_X^2) \). The existence of such a \( \sigma_j^2 \) follows from the intermediate value theorem. To prove the uniqueness, we assume that there exists a \( \sigma_j^2 \neq \sigma_j^2 \) such that \( \frac{\partial G_j(\sigma_j^2)}{\partial \sigma_j^2} |_{\sigma_j^2=\sigma_j^2} = 0 \). Since both \( G_j(\sigma_j^2) \) and \( G_j(\sigma_j^2) \) are local maxima, there must exist a local minimum between \( \sigma_j^2 \) and \( \sigma_j^2 \), which leads to a contradiction. Therefore, \( G_j(\sigma_j^2) \) is a strictly increasing function of \( \sigma_j^2 \) from 0 to \( \sigma_j^2 \) and a strictly decreasing function of \( \sigma_j^2 \) from \( \sigma_j^2 \) to \( \sigma_X^2 \).

Now we proceed to show that the maximizers \( \sigma_j^2 \), \( j = 1, \ldots, L - 1 \), given in (19) are monotonically decreasing continuous functions of \( d_{[1,\ldots,j]+1} \) and monotonically increasing continuous functions of \( d_{[1,\ldots,j]} \); furthermore, the monotonicity is strict when \( \sigma_j^2 \in (0, \sigma_X^2) \). We shall focus on the claim regarding \( d_{[1,\ldots,j]+1} \) since the other one can be proved in a similar manner. Note that for \( d_{[1,\ldots,j]+1} \in \left( d_{[1,\ldots,j]+1}, d_{[1,\ldots,j]+1} \right) \), we have \( \sigma_j^2 = \sigma_j^2 \in (0, \sigma_X^2) \). To stress its dependence on \( d_{[1,\ldots,j]+1} \), we denote \( \sigma_j^2 \) as \( \sigma_j^2(d_{[1,\ldots,j]+1}) \). It is easy to see that

\[
\left( \frac{\sigma_j^2}{\sigma_X^2 - d_{[1,\ldots,j]+1} + \delta} \right) ^{-1} \geq \left( \frac{\sigma_j^2}{\sigma_X^2 - d_{[1,\ldots,j]} + \delta} \right) ^{-1}
\]

where \( \delta \) is a small positive number. Now by the analysis for case 3, we must have \( \sigma_j^2(d_{[1,\ldots,j]+1}) > \sigma_j^2(d_{[1,\ldots,j]+1} + \delta) \). Therefore, \( \sigma_j^2(d_{[1,\ldots,j]+1}) \) is a strictly monotonically decreasing function of \( d_{[1,\ldots,j]+1} \).

We shall prove that \( \sigma_j^2(d_{[1,\ldots,j]+1}) \) is a continuous function of \( d_{[1,\ldots,j]+1} \) by contradiction. Without loss of generality, we assume

\[
\sigma_j^2 \triangleq \lim_{d_{[1,\ldots,j]+1} \to d_{[1,\ldots,j]+1}} \sigma_j^2(d_{[1,\ldots,j]+1}) \neq \sigma_j^2(d_{[1,\ldots,j]+1})
\]
for some $\tilde{d}_{1,\ldots,j+1}$. Note that

$$
\left( \frac{\sigma^2_{X} \tilde{d}_{1,\ldots,j+1}}{\sigma^2_{X} - \tilde{d}_{1,\ldots,j+1}} + \sigma^2 \right)^{-1} \left( \frac{\sigma^2_{X} \tilde{d}_{1,\ldots,j}}{\sigma^2_{X} - \tilde{d}_{1,\ldots,j}} + \sigma^2 \right)^{-1} \left( \frac{\sigma^2_{X} \tilde{d}_{j+1}}{\sigma^2_{X} - \tilde{d}_{j+1}} + \sigma^2 \right)^{-1}
$$

$$
= \lim_{d_{1,\ldots,j+1}\to\tilde{d}_{1,\ldots,j+1}} \left( \frac{\sigma^2_{X} \tilde{d}_{1,\ldots,j+1}}{\sigma^2_{X} - d_{1,\ldots,j+1}} + \sigma^2_{j} \left( d_{1,\ldots,j+1} \right) \right)^{-1}
+ \sigma^2 \left( d_{1,\ldots,j+1} \right)^{-1}
$$

which is contradictory with the analysis for case 3.

By leveraging the analysis for case 1 and case 2, one can use a similar argument to show that $\hat{d}_{1,\ldots,j+1} = d_{1,\ldots,j+1}$ as $d_{1,\ldots,j+1} \to \tilde{d}_{1,\ldots,j+1}$ and $\hat{d}_{1,\ldots,j+1} \to \tilde{d}_{1,\ldots,j+1}$ as $d_{1,\ldots,j+1} \to \tilde{d}_{1,\ldots,j+1}$ (if $d_{1,\ldots,j+1} \geq 0$). The proof is complete.

**APPENDIX C**

**PROOF OF LEMMA 3**

Consider the following procedure.

1) Initialization: $j = 1$ and $\tilde{d}_{1} = d_{1}$.

2) Let $\sigma^2_{j}$ be a maximizer to the optimization problem shown at the bottom of the page. If $\sigma^2_{j} = 0$, then set $\hat{d}_{j+1} = d_{j+1}$ and $\hat{d}_{1,\ldots,j+1} = d_{1,\ldots,j+1}$ if $\sigma^2_{j} = \sigma^2_{X}$, then set

$$
\hat{d}_{1,\ldots,j+1} = \left( \frac{\sigma^2_{X}}{\sigma^2_{j}} \right) \left( d_{1,\ldots,j+1} \right) + \sigma^2_{X} - \hat{d}_{1,\ldots,j+1}
$$

and

$$
\hat{d}_{1,\ldots,j+1} = d_{1,\ldots,j+1};
$$

otherwise set

$$
\hat{d}_{1,\ldots,j+1} = \hat{d}_{1,\ldots,j+1}.
$$

3) If $j = L - 1$, then stop; otherwise increase $j$ by one and go to 2).

It can be verified that the resulting $\hat{d}_{i}$, $i = 1, \ldots, L$, and $\hat{d}_{1,\ldots,i}$, $i = 2, \ldots, L$, have the desired property.

**APPENDIX D**

**PROOF OF LEMMA 5**

Consider the objective function

$$
Q(d_{1,\ldots,i}) = \frac{\alpha_{i}}{2} \log \left( \frac{\sigma^2_{X} d_{1,\ldots,i} - d_{1,\ldots,i} \sigma^2_{i-1}}{\sigma^2_{X} - d_{1,\ldots,i} \sigma^2_{i-1}} \right) + \frac{\alpha_{i}}{2} \log \left( \frac{\sigma^2_{X} d_{1,\ldots,i} - d_{1,\ldots,i} \sigma^2_{i-1}}{\sigma^2_{X} - d_{1,\ldots,i} \sigma^2_{i-1}} \right)
$$

$$
= \frac{\alpha_{i}}{2} \log \left( \frac{\sigma^2_{X} d_{1,\ldots,i} - d_{1,\ldots,i} \sigma^2_{i-1}}{\sigma^2_{X} - d_{1,\ldots,i} \sigma^2_{i-1}} \right) + \frac{\alpha_{i}}{2} \log \left( \frac{\sigma^2_{X} d_{1,\ldots,i} - d_{1,\ldots,i} \sigma^2_{i-1}}{\sigma^2_{X} - d_{1,\ldots,i} \sigma^2_{i-1}} \right)
$$

One can easily verify the second equation at the bottom of the page.

1) Case 1: $\alpha_{i} > \alpha_{i+1}$ and $\alpha_{i} \sigma^2_{X} (\sigma^2_{i} - \sigma^2_{i-1}) < \alpha_{i} \sigma^2_{i-1} (\sigma^2_{i} - \sigma^2_{i-1})$. We have $\frac{\partial Q(d_{1,\ldots,i})}{\partial d_{1,\ldots,i}} < 0$ for all $d_{1,\ldots,i} \in \left( 0, d'_{1,\ldots,i} \right)$. Therefore, the minimum is attained at $d_{1,\ldots,i} = d'_{1,\ldots,i}$.

2) Case 2: $\alpha_{i} > \alpha_{i+1}$ and $\alpha_{i} \sigma^2_{X} (\sigma^2_{i} - \sigma^2_{i-1}) > \alpha_{i} \sigma^2_{i-1} (\sigma^2_{i} - \sigma^2_{i-1})$. We have $\frac{\partial Q(d_{1,\ldots,i})}{\partial d_{1,\ldots,i}} > 0$ for all $d_{1,\ldots,i} \in \left( 0, d'_{1,\ldots,i} \right)$, where $d'_{1,\ldots,i} = \frac{(\alpha_{i} - \alpha_{i+1}) \sigma^2_{X} \sigma^2_{i-1} - \alpha_{i} \sigma^2_{i-1} (\sigma^2_{i} - \sigma^2_{i-1})}{\alpha_{i} \sigma^2_{X} (\sigma^2_{i} - \sigma^2_{i-1})}$.

Therefore, the minimum is attained at $d_{1,\ldots,i} = \min \left\{ d_{1,\ldots,i}, d'_{1,\ldots,i} \right\}$.

3) Case 3: $\alpha_{i} > \alpha_{i+1}$ and $\alpha_{i} \sigma^2_{i} < \alpha_{i} \sigma^2_{i-1}$. We have $\frac{\partial Q(d_{1,\ldots,i})}{\partial d_{1,\ldots,i}} > 0$ for all $d_{1,\ldots,i} \in \left( 0, d'_{1,\ldots,i} \right)$, where $d'_{1,\ldots,i} = 0$.

4) Case 4: $\sigma^2_{i} = \sigma^2_{i+1} = 0$. The objective function is a constant.

5) Case 5: $\alpha_{i} = \alpha_{i+1}$ and $\sigma^2_{i} > \sigma^2_{i-1}$. We have $\frac{\partial Q(d_{1,\ldots,i})}{\partial d_{1,\ldots,i}} < 0$ for all $d_{1,\ldots,i} \in \left( 0, d'_{1,\ldots,i} \right)$. Therefore, the minimum is attained at $d_{1,\ldots,i} = d'_{1,\ldots,i}$.

6) Case 6: $\alpha_{i} = \alpha_{i+1}$ and $\sigma^2_{i} < \sigma^2_{i-1}$. We have $\frac{\partial Q(d_{1,\ldots,i})}{\partial d_{1,\ldots,i}} > 0$ for all $d_{1,\ldots,i} \in \left( 0, d'_{1,\ldots,i} \right)$. Therefore, the minimum is attained at $d_{1,\ldots,i} = 0$.

7) Case 7: $\alpha_{i} = \alpha_{i+1}$ and $\sigma^2_{i} = \sigma^2_{i+1}$. The objective function is a constant.
APPENDIX E
CHARACTERIZATION OF THE SADDLE POINT

We shall assume throughout this appendix that all the distortion constraints are less than \( \sigma_X^2 \).

The saddle point is in general unique. To see this, consider two saddle points \((d_{[1,2]}, \ldots, d_{[1,\ldots,L-1]}, \sigma^2_1, \ldots, \sigma^2_{L-1})\) and \((d'_{[1,2]}, \ldots, d'_{[1,\ldots,L-1]}, \sigma'^{2}_1, \ldots, \sigma'^{2}_{L-1})\). We must have \( \psi(d_{[1,2]}, \ldots, d_{[1,\ldots,L-1]}, \sigma^2_1, \ldots, \sigma^2_{L-1}) \geq \psi(d'_{[1,2]}, \ldots, d'_{[1,\ldots,L-1]}, \sigma'^{2}_1, \ldots, \sigma'^{2}_{L-1}) \) and the first inequality becomes equality if and only if \( \sigma_j^2 = \sigma_j'^{2} \), \( j = 1, \ldots, L - 1 \). Furthermore, unless \( \sigma^2_{L-1} = \sigma'^{2}_{L-1} = 0 \) or \( \alpha_i = \alpha_i' \), \( \sigma^2_{i-1} = \sigma_{i-1}' \), we must have \( d_{[1,\ldots,i]} = d'_{[1,\ldots,i]} \) for \( i = 2, \ldots, L - 1 \). Note that if there exists an \( i \) such that \( d_{[1,\ldots,i]} \neq d'_{[1,\ldots,i]} \), we can find an \( i' < i \) such that \( \sigma^2_{i'-1} = \sigma_{i'-1}' \neq d'_{[1,\ldots,i'-1]} \) and \( \sigma^2_{i'-1} = \sigma_{i'-1} \) (cf. (19)). Therefore, it is possible to have \( d_{[1,\ldots,i]} \neq d_{[1,\ldots,i]} \) only when \( \sigma^2_{i'-1} = 0 \) or \( \alpha_i = \alpha_{i+1} \), \( \sigma^2_{i'-1} = \sigma_{i'-1}^2 \neq \sigma_{i'-1}' \).

We also have the following results.

Proposition 1: Let \((d_{[1,2]}, \ldots, d_{[1,\ldots,L-1]}, \sigma^2_1, \ldots, \sigma^2_{L-1})\) be a saddle point. We must have \( d_{[1,\ldots,i]} > 0 \), \( i = 2, \ldots, L - 1 \).

Proof: If \( d_{[1,\ldots,i]} = 0 \), we cannot have \( \sigma^2_j = 0 \) (cf. (19)), which implies \( \sigma^2_{i-1} = 0 \) (cf. (34) and (35)). Moreover, in view of (19) and the fact that \( d_{[i]} > 0 \), one can readily show that \( d_{[1,\ldots,i]} = 0 \) if \( \sigma^2_{i-1} = 0 \) and \( d_{[1,\ldots,i-1]} = 0 \). Now it follows by induction that \( d_{[1]} = 0 \), which results in a contradiction.

Remark: If \( d_{[1,\ldots,i]} = 0 \) for some \( i \), then we have
\[
\psi(d_{[1]}, \ldots, d_{[L]}, d_{[1,2]}, \ldots, d_{[1,\ldots,L]}, \sigma^2_1, \ldots, \sigma^2_{L-1}) = \infty.
\]
On the other hand, it follows by Theorem 3 that
\[
\psi(d_{[1]}, \ldots, d_{[L]}, d_{[1,2]}, \ldots, d_{[1,\ldots,L]}, \sigma^2_1, \ldots, \sigma^2_{L-1}) = \kappa(\sigma^2_1, \ldots, \sigma^2_{L-1}) \]
which is clearly finite. This gives an alternative proof of Proposition 1.

Proposition 2: Let \((d_{[1,2]}, \ldots, d_{[1,\ldots,L-1]}, \sigma^2_1, \ldots, \sigma^2_{L-1})\) be a saddle point. If \( \sigma^2_{i^* - 1} = 0 \) for some \( i^* \), then \( \sigma^2_{i^*} = 0 \) for all \( i \geq i^* \).

Proof: If \( \sigma^2_{i^*} > 0 \), then we have \( \alpha_{i^*+1}\sigma^2_1(\sigma^2_X - \sigma^2_{i-1}) > \alpha_{i^*}\sigma^2_{i-1}(\sigma^2_X - \sigma^2_{i-1}) > \sigma^2_{i-1}(\sigma^2_X - \sigma^2_{i-1}) \). It follows by (34) and (35) that \( d_{[1,\ldots,i^*]} = 0 \), which leads to a contradiction with Proposition 1. Therefore, we must have \( \sigma^2_{i^*} = 0 \). The proof is complete by induction.

Now we proceed to give a more explicit characterization of the saddle point \((d_{[1,2]}, \ldots, d_{[1,\ldots,L-1]}, \sigma^2_1, \ldots, \sigma^2_{L-1})\) for the case where only individual and central distortion constraints are imposed. We shall set \( d_{[1,\ldots,i]} = \min_{j \in [1,\ldots,i]} d_{[j]} \), \( i = 2, \ldots, L - 1 \), to make the auxiliary distortion constraints redundant.

First, one can make the following two observations by inspecting (19), (34), and (35).

1) If \( \alpha_i > \alpha_{i+1} \) for some \( i \geq 2 \), then either \( \sigma^2_{i-1} = \sigma^2_i = 0 \) or \( \alpha_{i+1}\sigma^2_1(\sigma^2_X - \sigma^2_{i-1}) > \alpha_i\sigma^2_{i-1}(\sigma^2_X - \sigma^2_{i-1}) \) (which further implies \( \sigma^2_{i-1} > \sigma^2_{i-1} \). Moreover, if \( \alpha_{i+1} > \alpha_i \), then \( \sigma^2_{i-1} = \sigma^2_i \).

2) If \( \alpha_i = \alpha_{i+1} \) for some \( i \geq 2 \), then \( \sigma^2_{i-1} = \sigma^2_i \).

These two observations, together with Proposition 2, lead to the following classification.

1) Case 1: \( \sigma^2_1 = \cdots = \sigma^2_{L-1} = 0 \). We must have
\[
d_{[1,\ldots,i]} \leq \left( \frac{1}{d_{[1,\ldots,i-1]}} + \frac{1}{d_{[i]}} \right)^{-1} \sigma^2_X, \quad \text{if } i = 2, \ldots, L - 1
\]
which implies \( d_{[1,\ldots,L]} \geq \sigma^2_X \).

2) Case 2: \( 0 < \sigma^2_1 \leq \cdots \leq \sigma^2_{i^*} < \sigma^2_X \). The saddle point is uniquely determined by
\[
\left( \frac{\sigma^2_1 d_{[1,\ldots,i]} + \sigma^2_{i-1}}{\sigma^2_X - d_{[1,\ldots,i-1]}} \right)^{-1} = \left( \frac{\sigma^2_1 d_{[i]} + \sigma^2_{i-1}}{\sigma^2_X - d_{[i]}} \right)^{-1} + \left( \frac{\sigma^2_{i-1}}{\sigma^2_X - d_{[i]}} \right)^{-1}, \quad i = 2, \ldots, L
\]

3) Case 3: \( 0 < \sigma^2_1 \leq \cdots \leq \sigma^2_{i^*} < \sigma^2_X \). If \( \alpha_i = \alpha_{i+1} \), \( i = 1, 2, \ldots, L - 1 \), and \( d_{[1,\ldots,i]} \), \( i = 2, \ldots, i^* \), are uniquely determined by
\[
\left( \frac{\sigma^2_1 d_{[1,\ldots,i]} + \sigma^2_{i-1}}{\sigma^2_X - d_{[1,\ldots,i-1]}} \right)^{-1} = \left( \frac{\sigma^2_1 d_{[1,\ldots,i]} + \sigma^2_{i-1}}{\sigma^2_X - d_{[1,\ldots,i-1]}} \right)^{-1} + \left( \frac{\sigma^2_1 d_{[i]} + \sigma^2_{i-1}}{\sigma^2_X - d_{[i]}} \right)^{-1} + \left( \frac{\sigma^2_{i-1}}{\sigma^2_X - d_{[i]}} \right)^{-1}, \quad i = 2, \ldots, i^*.
\]
while \( d_{1,\ldots,i^*}, \ i = i^* + 1, \ldots, L - 1 \), must satisfy
\[
d_{1,\ldots,i^*} \geq d_{1,\ldots,i^*+1} - d_{i^*+1} + \sigma^2_X, \quad i = i^*, \ldots, L - 1. \tag{47}
\]

Note that \( d_{1,\ldots,L} \) does not appear in (43), (44), (45), and (46). Therefore, given \( d_{i^*}, \ i = 1, \ldots, L \), we can increase \( d_{1,\ldots,i^*} \) without affecting \( \sigma^2_i, \ i = 1, \ldots, L - 1 \), and \( d_{1,\ldots,i^*}, \ i = 2, \ldots, i^* \), until
\[
d_{1,\ldots,i^*} = d_{1,\ldots,i^*} + \sum_{i=i^*+1}^L d_i - (L-i^*)\sigma^2_X.
\]

Denote this critical \( d_{1,\ldots,i^*} \) by \( d_{1,\ldots,L} \). If we further increase \( d_{1,\ldots,L} \), then the \( d_{1,\ldots,i^*} \) induced by (43), (44), (45), and (46) cannot satisfy (47) anymore, and we enter the regime covered by case 2. It is worth noting that
\[
d_{1,\ldots,L} = \sum_{i=1}^L d_i - (L-1)\sigma^2_X
\]
when \( \alpha^2 = \cdots = \alpha_L \).

REFERENCES

Jun Chen (S’03–M’06) received the B.E. degree with honors in communication engineering from Shanghai Jiao Tong University, Shanghai, China, in 2001, and the M.S. and Ph.D. degrees in electrical and computer engineering from Cornell University, Ithaca, NY, in 2003 and 2006, respectively.
